The Gaussian Distribution

A continuous d -variate random vector $\mathbf{X} = (X_1, \dots, X_d)^T$ is **normally distributed**, written $\mathbf{X} \sim \mathcal{N}(\boldsymbol{\mu}, \Sigma)$, when its joint pdf is:

$$p(\mathbf{x}) = \frac{1}{(2\pi)^{\frac{d}{2}} |\Sigma|^{\frac{1}{2}}} \exp \left\{ -\frac{1}{2} (\mathbf{x} - \boldsymbol{\mu})^T \Sigma^{-1} (\mathbf{x} - \boldsymbol{\mu}) \right\}$$

where $\boldsymbol{\mu}$ is the *mean vector* and $\Sigma_{d \times d} = (\sigma_{ij}^2)$ is the (real symmetric and p.d.) *covariance matrix*.

- $\mathbb{E}[\mathbf{X}] = \boldsymbol{\mu}$ and $\mathbb{E}[(\mathbf{X} - \boldsymbol{\mu})(\mathbf{X} - \boldsymbol{\mu})^T] = \Sigma$.
- $\text{CoVar}[X_i, X_j] = \sigma_{ij}^2$ and $\text{Var}[X_i] = \sigma_{ii}^2$

if $\mathbf{X} \sim \mathcal{N}(\boldsymbol{\mu}, \Sigma)$, then X_i, X_j are independent $\iff \text{CoVar}[X_i, X_j] = 0$

(in general, only the left-to-right implication holds)

The Gaussian Distribution ($d = 2$)

The Gaussian Distribution ($d = 2$)

Observations from a bivariate normal distribution, a contour ellipsoid, the two marginal distributions, and their histograms (images from the Wikipedia)

The Gaussian Distribution ($d = 2$)

$$\mu = \begin{bmatrix} 3 \\ 3 \end{bmatrix} \quad \Sigma = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

$$\Sigma = \begin{bmatrix} 0.1 & 0 \\ 0 & 1 \end{bmatrix}$$

$$\Sigma = \begin{bmatrix} 1 & 0.5 \\ 0.5 & 1 \end{bmatrix}$$

- The principal directions (a.k.a. PCs) of the hyperellipsoids are given by the *eigenvectors* \mathbf{u}_i of Σ , which satisfy $\Sigma \mathbf{u}_i = \lambda_i \mathbf{u}_i$.
- The lengths of the hyperellipsoids along these axes are proportional to $\sqrt{\lambda_i}$ (note $\lambda_i > 0$)

- What is behind the choice of a **multivariate Gaussian**?

Examples from a class are noisy versions of an ideal class member (a *prototype*):

- Prototype: modeled by the mean vector
 - Noise: modeled by the covariance matrix
- The quantity

$$d(\mathbf{x}) := \sqrt{(\mathbf{x} - \boldsymbol{\mu})^T \boldsymbol{\Sigma}^{-1} (\mathbf{x} - \boldsymbol{\mu})}$$

is called the **Mahalanobis distance** for \mathbf{x}

- Very important! the number of parameters is $\frac{d(d+1)}{2} + d$

Mathematical view

Positive definiteness

For a Gaussian distribution to be well-defined, Σ has to be real symmetric and positive definite (p.d.): for all non-null vectors $\mathbf{x} \in \mathbb{R}^d$, $\mathbf{x}^T \Sigma \mathbf{x} > 0$ must hold true

Examples: are these matrices p.d.?

$$a. \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

$$b. \begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & 1 \end{pmatrix}$$

$$c. \begin{pmatrix} 3 & -1 \\ -1 & 2 \end{pmatrix}$$

$$d. \begin{pmatrix} 1 & 4 \\ \frac{1}{2} & 1 \end{pmatrix}$$

a. YES;

b. YES

c. YES;

d. NO

Evolution Strategies: main characteristics

- Continuous search space \mathbb{R}^n
- Various recombination operators
- Deterministic (μ, λ) -replacement
- Emphasis on mutation: n -dimensional Gaussian, zero expectation
- Self-adaptation of mutation parameters (first self-adaptive EA!)
- Generation of an offspring surplus $\lambda \gg \mu$

Evolution Strategies: Representation

- ① **objective** space: $\mathcal{O} := \mathbb{R}^n$
- ② **strategy** space (stdevs and angles of mutation):

$$\mathcal{P} := \mathbb{R}_+^{n_\sigma} \times (-\pi, \pi]^{n_\alpha}$$

The three parts of an individual

- ① object variables $\mathbf{x} \in \mathbb{R}^n$ to compute fitness $F(\mathbf{x})$
- ② standard deviations $\boldsymbol{\sigma} \in \mathbb{R}_+^{n_\sigma}$ to express variances
- ③ rotation angles $\boldsymbol{\alpha} \in (-\pi, \pi]^{n_\alpha}$ to express covariances

Simple Self-Adaptive Mutation

$n_\sigma = 1, n_\alpha = 0$ (one mutation parameter per individual)

- ① $\sigma := \sigma \cdot \exp(\mathcal{N}(0, \tau_0))$
- ② $x_i := x_i + \mathcal{N}_i(0, \sigma^2), 1 \leq i \leq n$

where

$$\tau_0 \propto \frac{1}{n}$$

Evolution Strategies: Mutation (I)

Simple self-adaptive Mutation ($n = 2$)

equal probability to place an offspring

Diagonal self-adaptive Mutation

$n_\sigma = n, n_\alpha = 0$ (one mutation parameter per individual and variable)

① $\sigma_i := \sigma_i \cdot \exp(\mathcal{N}(0, \tau') + \mathcal{N}_i(0, \tau))$

② $x_i := x_i + \mathcal{N}_i(0, \sigma_i^2), 1 \leq i \leq n$

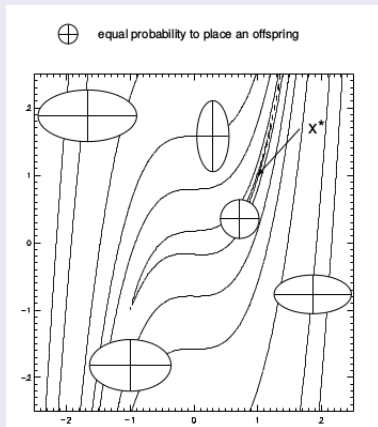

where

$$\tau \propto \frac{1}{2\sqrt{n}}$$

$$\tau' \propto \frac{1}{2n}$$

Evolution Strategies: Mutation (II)

Diagonal Self-Adaptive Mutation ($n = 2$)

Evolution Strategies: Mutation (III)

Correlated self-adaptive Mutation

$n_\sigma = n, n_\alpha = \frac{n(n-1)}{2}$ (one covariance matrix per individual)

- 1 $\sigma_i := \sigma_i \cdot \exp(\mathcal{N}(0, \tau') + \mathcal{N}_i(0, \tau))$
- 2 $\alpha_i := \alpha_i + \mathcal{N}_i(0, \beta^2), 1 \leq i \leq n$
- 3 Build Σ using the σ and α for individual \mathbf{x}
- 4 $\mathbf{x} := \mathbf{x} + \mathcal{N}(0, \Sigma)$

where

$$\tau \propto \frac{1}{2\sqrt{n}}$$

$$\tau' \propto \frac{1}{2n}$$

$$\beta \propto 5^\circ \text{ } (\pi/36 \text{ radians})$$

Evolution Strategies: Mutation (III)

Correlated Self-Adaptive Mutation ($n = 2$)

equal probability to place an offspring

Evolution Strategies: Mutation (III)

Illustration of the mutation ellipsoid for the case ($n = 2$)

Evolution Strategies: Mutation (III)

Theorem

A real symmetric matrix $A_{n \times n}$ is P.D. iff it can be decomposed as $A = T^T D T$, with T orthogonal and D diagonal with positive entries:

$$T = \prod_{i=1}^{n-1} \prod_{j=i+1}^n R_{ij}(\alpha_{ij})$$

- T is the product of $\frac{n(n-1)}{2}$ elementary rotation matrices
- α_{ij} are the rotation angles (between axes i and j)
- $R_{ij}(\alpha)$ is build as the identity matrix and modified as:

$$\begin{aligned} [R_{ij}(\alpha)]_{ii} &= [R_{ij}(\alpha)]_{jj} := \cos(\alpha) \\ [R_{ij}(\alpha)]_{ij} &= -[R_{ij}(\alpha)]_{ji} := -\sin(\alpha) \end{aligned}$$

log-normal distribution

It is a continuous probability distribution whose logarithm is normally distributed. A random variable which is log-normally distributed takes only positive real values.

$$\sigma_i := \sigma_i \cdot \exp(\mathcal{N}(0, \tau'))$$

- 1 Multiplication by positive values preserves positivity
- 2 $Pr\{x\} = Pr\{\frac{1}{x}\}, x > 0$
- 3 Small modifications are more probable than larger ones

Evolution Strategies: recombination (I)

- Usually introduced as the *first* operator
- Generates an intermediate population size of λ by generating one individual at a time out of ξ parents by looping $\lambda \gg \mu$ times (generation of a **surplus**)
- Typically $\xi = 2$ (**dual**) or $\xi = \mu$ (**global** recombination):
 - dual**: the two parents are chosen at random, per individual
 - global**: one parent is held fixed and the other is chosen anew per each gene
- Applied to both objective and strategy parameters (and often differently)
- Two basic ways: choose randomly (**discrete**) and average (**intermediate**)

Evolution Strategies: recombination (II)

recombination example

- $\mu = 6, n = 5, n_\sigma = n, n_\alpha = 0$ (one mutation parameter per individual and gene)
- dual discrete recombination on x_i ; global intermediate on σ_i (first parent held fixed, second chosen anew)

Evolution Strategies: replacement

- Strictly deterministic, rank-based
- The μ best are treated equally
- (μ, λ) selection:
 - offspring surplus $\lambda \gg \mu$
 - important (necessary?) for self-adaptation
 - useful for moving optima, noisy F , ...

⇒ Very strong selective pressure

The crucial claim (Schwefel '87 '92)

Self-adaptation of strategy parameters works

- without exogenous or centralized control
- needs mutation of all parameters
- needs generation of a surplus and (μ, λ) replacement
- needs recombination of all parameters

default (recommended) settings:

- $\mu = 15, \lambda \propto 7\mu = 105$
- dual discrete recombination on objective parameters
- global intermediate on strategy parameters

Evolution Strategies: Modern developments

The CMA-ES (Covariance Matrix Adaptation Evolution Strategy) is the more recent development of ESs

- It uses a sophisticated method to update the covariance matrix, particularly useful if the fitness function is complex
- Adaptation of the covariance matrix amounts to learning a second order model of the underlying function (similar to the approximation of the inverse Hessian matrix in quasi-Newton methods)
